Excerpt: . . . fact that the patient is nauseated and holding his breath, and on the point of vomiting. If, however, the patient is cyanosed and the abdominal muscles are relaxed and flabby, it is usually a danger signal, and you will find that either the respiratory or cardiac centers are failing to act. Occasionally during anesthesia, where there is some difficulty in respiration, it has been found that on drawing the tongue upward and forward, which is the usual method of freeing the epiglottis, instead of adding to the patients comfort and relieving the obstruction to breathing, it has increased it. It has been my privilege to see several such cases. On examination it was found that the anterior portion of the axis and atlas, and in another instance the second vertebra--the anterior portion extended forward, in other words--was so enlarged that it produced an offset in the pharynx at such a point that when the tongue was drawn forward and the larynx elevated it pressed the epiglottis against this protruding pharyngeal wall, showing that in all cases the method of drawing the tongue forward and upward is not applicable. The most convenient mouth-gag for use in operations about the pharynx is shown in Fig. 178. It is easily retained, not in the way, and can in no wise injure the teeth. The rectal method of administering ether, as suggested by Cunningham and Stucky, certainly would be of great advantage in certain major operations about the...
